1 Introduction

The Physics Derivation Graph is a project designed to capture mathematical physics knowledge.

Historically, knowledge about physics has been recorded in the form of notes, letters, journal articles, and text books. The content is typically composed of text, equations, and pictures. The presentation is in a linear sequence, though references are made to link the current section with previous sections and later sections.

A recent addition has been the use of webpages to capture knowledge. A primary example of this is Wikipedia, an HTML-based encyclopedia. Webpages such as Wikipedia still use text, equations, and pictures, but add a distinct capability: hyperlinks. Hypertext Markup Language offers the ability to connect content to any other content. This enables non-linear exploration of content, in contrast to a text-book which is designed to be read sequentially.

The Physics Derivation Graph is a non-linear capture of knowledge with mathematically-based links of physics content. A graph is composed of node and edges. This graph has two types of nodes: mathematical statements and inference rules. Every mathematical statement (referred to here as a statement) is connected to an inference rule by a directed edge. An example is provided which illustrates the concepts.

Frequency f and period T are related by

$$T f = 1 \quad (1)$$

Thus, frequency in terms of the period is

$$f = 1/T \quad (2)$$

The relation between Eq. (1) and Eq. (2) is that both sides of Eq. (1) were divided by T .

In the above example, there are two mathematical statements: Eq. (1) and Eq. (2). These statements

are related by an inference rule: “Divide both sides of first equation by a value to yield the second equation.” This inference rule takes an argument, referred to here as the “feed”, which in this example is T . This set of steps is shown graphically in Fig. ??

1.1 Scope of Project

The core of this project is capturing the graph associated with mathematical physics. Once this is available, there are many potential tasks. The following section provides a specific set of stages for the research. Not expected within the scope of the graph are inclusion of graphics, explanatory text, animations of concepts, and interactive models.

Tasks in section 2 such as checking the validity of the graph using a Computer Algebra System, visualization of the graph, and interactivity of input are follow-on tasks once the graph content has been developed to describe mathematical physics.

1.2 Distribution of Content

The Physics Derivation Graph is free and open source under the Creative Commons Attribution-ShareAlike 3.0 Unported license. This content is free because it is intended to be accessible to anyone; cost should not be a barrier to access. The content is open source so that other researchers can build upon what exists. Once content is built, it should not need to be built again.

1.3 Similar Projects

The scope and intention of the Physics Derivation Graph is unique, though aspects are shared by several active projects. Four examples are provided in

*Corresponding author: ben.is.located@gmail.com

this section: HyperPhysics, EquationMap, Formula Database, and Symbolab. The purpose is not to review these projects for utility or to comprehensively survey similar projects. Instead, they are used here to contrast the scope and intention of the Physics Derivation Graph.

The HyperPhysics website[1] is a static set of linked concept maps for topics in Physics. Concept maps are linked to text, graphs, and equations. The licensing of the content is described as “not freeware or shareware” by the author, though the site is free to access. Although hyperlinked concept maps are a departure from the standard textbook presentation of physics, the leaves of this tree are the same content found in textbooks.

The website EquationMap[2] is an interface for derivations, focused primarily on mathematical sciences. There is no backend database of content; instead content is dynamically generated by the user. Equations are manually entered using \LaTeX syntax and the graph of the derivation can be visualized using the same interface. The content is not open source and access is currently free. This is close to what the GUI for the Physics Derivation Graph is intended to behave like, with the exception that EquationMap doesn’t include the concept of atomic inference rules.

Formula Database[3] is a website described by the authors as a “math search engine” which has a built-in equation editor. The search feature is not just matching the Latex input – it understands dot product and cross product. They have created a browser-based equation editor, similar to the equation editor in Microsoft Word. The search is of a backend database of content. The backend database of equations and symbols was manually entered by the project authors. A team of people have been working since about 2010 on this project. The data is stored as a high-dimensional graph. This project is not open source but access is currently free. A commercial launch is planned, though no date has been publicized.

The objective is to allow students to search through literature. If you are a researcher, you might want to find whether the model already exists in literature. The grand view is that formula-database will serve as a universal reference for equations.

SymboLab[4] is another backend database of content. This project is not open source but access is currently free.

Wolfram Alpha[5] has a backend database of content which is not open source; access is a mix of free and paid.

2 Development Stages

This project is expected to evolve through distinct steps. Each step can be characterized by different users and associated requirements.

The first step is prototyping and involves a small number of expert users interested in gathering content for the Physics Derivation Graph. This exploratory phase involves research on appropriate syntax for the graph, brainstorming use cases, and minimal interaction with an external community.

The second phase is when sufficient examples exist to constitute a proof of concept. This requires breadth of coverage across all the domains of physics (*i.e.*, classical mechanics, quantum mechanics, relativity, thermodynamics, statistical mechanics, etc). As a consequence, much of mathematics covered up to undergraduate level is likely to be required.

Once the breadth of coverage is demonstrated, the next step is to enable development of indepth creation for the Physics Derivation Graph. Currently, content is manually entered into an XML database, and visualization of the graph is generated via the command line. To make both data entry and visualization more accessible to users and developers, a web browser-based interaction is planned. As noted in section 1.1, this is outside of the project scope regarding graph content, but would make additions more accessible.

The most difficult step may be adoption and utilization by the scientific and education communities. This widespread use is dependent on having useful and reliable content, intuitive interfaces, and addresses a need. The Physics Derivation Graph does not currently exist, implying the needs being addressed are either unclear or sufficiently complex to make solution difficult.

The steps listed above are sequential, but will likely be worked on concurrently. Exploration of an intuitive interface can take place while examples are being gathered. In the next section, use cases which motivate users of this project are described.

3 Use Cases

While curiosity has driven the development of the Physics Derivation Graph, the resulting work is expected to be useful to multiple audiences and users. Viewers of the content could include students in math and physics, and analysis of the content could help shape curriculum. Contributors to the Physics Derivation Graph would be scientists who add new developments based on their work.

3.1 Students in Math and Physics

Currently students in Math and Physics are taught content using lectures, textbooks, and homework. The method of presentation varies, but the overarching story is often historically driven. Algebra is old, calculus is newer, and topology is recent. Classical mechanics is old, thermodynamics is newer, and quantum mechanics is recent. When teaching, these subjects are taught by building on previous content – calculus leverages algebra, thermodynamics leverages classical mechanics.

3.2 Scientific Articles

Peer-reviewed journal articles are one of the current methods of demonstrating value in the scientific community. Conciseness is a feature of this writing style, and the mathematics presented is correspondingly sparse – just sufficient to convey the author’s intention. This results in a burden on the reader of the article, either to take the author’s claims on faith, or to rederive the mathematical statements. A reader’s derivation is complicated by implicit assumptions made by the author and unintentional mistakes in calculation.

With journals allowing supplemental materials for articles, calculations could be included. However, it is not clear what the appropriate level of detail is in supplied calculations. The intention is to be able to reproduce the work, but

validation via computer

3.3 Education Curriculum Design

A less direct use case but potentially important impact of the Physics Derivation Graph is on understanding the relevance of what is being taught in the education system. Math classes essentially teach a

set of inference rules, and physics is the application of those inference rules. The Physics Derivation Graph could answer two important questions: “When am I going to use this inference rule?” and “What’s the relative importance of this math skill?”

The focus for students in mathematics classes is on the technique, *i.e.*, “integrate both sides with respect to Y ,” and application is necessarily of secondary importance. Physics students are expected to know the mathematical techniques and teaching is focused on application. The Physics Derivation Graph can assist both scenarios. The student in a math class can see where the inference rules they learn are applied in Physics. The student in the Physics class can see which inference rules are required in their field.

Each inference rule seems equally important, since it currently isn’t known what the frequency of use for that inference rule is. From the Physics Derivation Graph, it is simple to count utilization of inference rules. Thus, we are able to measure the ratio of how often “multiply both sides by X ” is used relative to “integrate both sides with respect to Y .”
